CONVERGENCE OF THE CELL AVERAGE TECHNIQUE FOR SMOLUCHOWSKI COAGULATION EQUATION

ANKIK KUMAR GIRI\textsuperscript{1,2,*} AND ATULYA K. NAGAR\textsuperscript{3}

ABSTRACT. We present the convergence analysis of the cell average technique, introduced in [19], to solve the nonlinear continuous Smoluchowski coagulation equation. It is shown that the technique is second order accurate on uniform grids and first order accurate on non-uniform smooth (geometric) grids. As an essential ingredient, the consistency of the technique is thoroughly discussed.

Mathematics subject classification (2010): 45J05, 45K05, 45L05, 65R20
Key-words: Particles; Coagulation; Cell average technique; Consistency; Lipschitz condition; Convergence.

1. Introduction

In this article we study some mathematical issues related to the convergence of the cell average technique (CAT) [19] for solving the continuous Smoluchowski coagulation equation (SCE) which describes the dynamic evolution of particle growth. This model has many applications in biology, polymer science, astrophysics and oil industry etc. The nonlinear continuous SCE reads as

\begin{equation}
\frac{\partial f(t,x)}{\partial t} = \frac{1}{2} \int_{0}^{x} \beta(x-y, y)f(t, x-y)f(t, y)dy - \int_{0}^{\infty} \beta(x, y)f(t, x)f(t, y)dy,
\end{equation}

with

\[ f(x, 0) = f_{\text{in}}(x) \geq 0, \quad x \in [0, \infty[. \]

Here the number density of particles of volume \(x > 0\) at time \(t \geq 0\) is denoted by \(f(x, t) \geq 0\). The coagulation kernel \(\beta(x, y) \geq 0\) represents the rate at which particles of volume \(x\) coalesce with particles of volume \(y\). It will be assumed throughout the article that \(\beta(x, y) = \beta(y, x)\) for all \(x, y > 0\), i.e. symmetric and \(\beta(x, y) = 0\) for either \(x = 0\) or \(y = 0\). The integrals on the right-hand side of (1.1) represent, respectively,

- **birth of particles of volume** \(x\) **as a result of coagulation events of** particles with volumes \(y\) and \(x - y\) \((0 \leq y \leq x)\)
- **death of particles of volume** \(x\) **due to the coagulation events with** particles of volume \(y\) \((0 \leq y < \infty)\).

There are several results available on the existence and uniqueness of solutions to (1.1), see e.g. [2, 4, 7, 14, 15, 16, 25, 26, 27, 30, 31, 35]. To show all these results, one always needs certain growth conditions on coagulation kernels. The SCE (1.1) is analytically solvable only for some specific examples of coagulation kernels, see [3, 11, 12]. Because of these restrictions, several researchers are always interested to solve such models by applying different numerical techniques with a detailed study of their mathematical analysis.

A large variety of numerical methods have been applied for solving SCE: finite element methods [8, 32, 33], finite volume methods [1, 9, 10], stochastic methods [5, 6, 28], moment methods [34] and sectional methods [19, 22, 23, 24]. Stochastic methods are very powerful to solve such problems. Otherwise, most of these methods may give a good approximation of number density but a poor approximation of moments. However, the moment methods approximate very accurately the moments of the number density but are unable to give a precise information about the number density. Among all these methods for solving SCE (1.1), the sectional methods have become very popular because they not only approximate accurately some selected moments but also give satisfactory results for the number density.

Among all sectional methods, the fixed pivot technique (FPT) [23] is most widely used method in the literature. In the FPT, each new born particle, which is not positioned at a pivot point of any cell has to be assigned onto the neighboring pivot points. A step to improve the existing sectional methods has been made in [19, 22] as the cell average technique (CAT). Unlike the FPT, here in the CAT, the average of all new born particles in a cell is assigned to the neighboring pivot points. In both of the methods, the reassignment is done in such a way that the total number and mass remain conserved. For solving the linear breakage/fragmentation equation, both FPT and CAT, in [20, 21], are shown second order accurate on uniform and non-uniform smooth meshes. Recently, in [17], it is shown that the FPT is second order accurate on uniform and non-uniform smooth grids for solving the nonlinear SCE.

The purpose of this work is to demonstrate the convergence analysis of CAT for solving SCE (1.2) on uniform and non-uniform smooth geometric grids. To the best of our knowledge, this is the first attempt to show the convergence of CAT for solving nonlinear continuous SCE. The work presented here is motivated from [17, 21].

To apply a numerical method, first we need to consider the following truncated form of the problem (1.1) by taking a finite computational domain \([0, R]\) where \(0 < R < \infty\).

\[
\frac{\partial n(t, x)}{\partial t} = \frac{1}{2} \int_0^x \beta(x - y, y)n(t, x - y)n(t, y)dy - \int_0^R \beta(x, y)n(t, x)n(t, y)dy,
\]

with \(n(x, 0) = n^\text{in}(x) \geq 0, \quad x \in \Omega := [0, R]\),

where \(n(t, x)\) represents the solution to the truncated equation (1.2). The existence and uniqueness of non-negative solutions for the truncated SCE (1.2) has been shown in [4, 35]. In [4, 7, 14, 16, 26, 35], it is proven that the sequence of solutions to the truncated problems
converge weakly to the solution of the original problem in a weighted $L^1$ space as $R \to \infty$ for certain classes of kernels.

The plan of this paper is as follows. The mathematical formulation of CAT is recalled in the next section. The main convergence result is stated as Theorem 2.6 at the end of Section 2. In order to prove the main result, the consistency of the method and Lipschitz conditions are investigated in Section 3 and 4, respectively. Finally, some conclusions are made in Section 5.

2. THE CELL AVERAGE TECHNIQUE

The cell average technique approximates the total number of particles in finite number of cells. As a first step, the continuous interval $\Omega := [0, R]$ is divided into a small number of cells defining size classes

$$\Lambda_i := [x_{i-1/2}, x_{i+1/2}], \; i = 1, \ldots, I,$$

with

$$x_{1/2} = 0, \quad x_{I+1/2} = R.$$  

The representative of each size class, usually the center point of each cell $x_i = (x_{i-1/2} + x_{i+1/2})/2$, is called pivot or grid point. We introduce $\Delta x_{\min}$ and $\Delta x \in [0, 1]$ to satisfy

$$\Delta x_{\min} \leq \Delta x_i = x_{i+1/2} - x_{i-1/2} \leq \Delta x.$$  

For the purpose of later analysis, we assume that there exists a positive constant $K$ (independent of grid) such that

$$\frac{\Delta x}{\Delta x_{\min}} \leq K. \quad (quasi \ uniformity)$$

The total number of particles in the $i$th cell is given as

$$N_i(t) = \int_{x_{i-1/2}}^{x_{i+1/2}} n(t, x) dx.$$  

(2.2)

Integrating the continuous equation (1.2) over the $i$th cell we obtain

$$\frac{dN_i(t)}{dt} = B_i - D_i, \quad i = 1, \ldots, I.$$  

(2.5)

The total birth rate $B_i$ and the death rate $D_i$ are given as

$$B_i = \frac{1}{2} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_0^x \beta(x - y, y)n(t, x - y)n(t, y)dydx,$$

(2.3)

and

$$D_i = \int_{x_{i-1/2}}^{x_{i+1/2}} \int_{x_{i-1/2}}^{x_{i+1/2}} \beta(x, y)n(t, y)n(t, x)dydx.$$  

(2.4)

The above equations yield a semi-discrete system in $\mathbb{R}^I$

$$\frac{d\mathbf{N}}{dt} = \mathbf{B} - \mathbf{D}, \quad \text{with} \quad \mathbf{N}(0) = \mathbf{N}^{in},$$

where $\mathbf{N}, \mathbf{B}, \mathbf{D} \in \mathbb{R}^I$. The $i$th component of vectors $\mathbf{N}, \mathbf{B},$ and $\mathbf{D}$ are respectively defined in (2.2)-(2.4). The vector $\mathbf{N}$ is formed by the vector of values of the step function obtained by
projection of the exact solution \( n \) into the space of step functions, which are constant on each cell. Note that this projection error can easily be shown of second order, see [13]. The total discrete birth and death rates of particles are evaluated by substituting the number density approximation

\[
n(t, x) \approx \sum_{i=1}^{l} N_i(t) \delta(x - x_i)
\]

into equations (2.3) and (2.4) as

\[
\hat{B}_i = \sum_{x_{i-1/2} \leq x_j + x_k < x_{i+1/2}} \left(1 - \frac{1}{2} \delta_{j,k}\right) \beta(x_k, x_j) N_j(t) N_k(t),
\]

and

\[
\hat{D}_i = N_i(t) \sum_{j=1}^{l} \beta(x_i, x_j) N_j(t).
\]

Here \( \hat{B}_i \) and \( \hat{D}_i \) denote the discrete birth and death rates, respectively, in the \( i \)th cell. The total volume flux \( V_i \) into cell \( i \) as a result of aggregation is given by

\[
V_i = \frac{1}{2} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_{0}^{x} x \beta(x - y, y)n(t, x - y)n(t, y)dydx.
\]

Similarly to the discrete birth rate the discrete volume flux can be obtained as

\[
\hat{V}_i = \sum_{x_{i-1/2} \leq x_j + x_k < x_{i+1/2}} \left(1 - \frac{1}{2} \delta_{j,k}\right) \beta(x_k, x_j) N_j(t) N_k(t)(x_j + x_k).
\]

Consequently, the average volume \( \bar{v}_i \in [x_{i-1/2}, x_{i+1/2}] \) of all new born particles in the \( i \)th cell can be evaluated as

\[
\bar{v}_i = \frac{\hat{V}_i}{\hat{B}_i}, \quad \hat{B}_i > 0.
\]

We do not need volume average \( \bar{v}_i \) in case of \( \hat{B}_i = 0 \). However, for \( \hat{B}_i = 0 \), we can fix \( \bar{v}_i = x_i \).

The main idea of the scheme is to assign temporarily all new born particles in the \( i \)th cell to the average volume \( \bar{v}_i \). If the average volume \( \bar{v}_i \) is same as the pivot point \( x_i \) then the total birth \( \hat{B}_i \) of the new born particles can be assigned to the pivot \( x_i \) only. But this is rarely possible, and hence, the total birth \( \hat{B}_i \) has to be assigned to the neighboring pivots in such a way that the total number and mass remain conserved during this reassignment. Finally, the resultant set of ODEs takes the following form

\[
\frac{d \hat{N}_i}{dt} = \hat{B}_i^{CA} - \hat{D}_i^{CA}.
\]

The above discretized system can also be written in the following vector form

\[
\frac{d \hat{N}}{dt} = \mathbf{B}(\hat{N}) - \mathbf{D}(\hat{N}) =: \mathbf{F}(t, \hat{N}), \quad \text{with} \quad \hat{N}(0) = \hat{N}^{in},
\]
where \( \mathbf{\hat{N}}, \mathbf{\hat{B}}, \mathbf{\hat{D}} \in \mathbb{R}^I \). The numerical approximation of total number of particles in \( i \)th cell, \( N_i(t) \), is defined by \( \hat{N}_i(t) \) which is the \( i \)th component of the vector \( \mathbf{\hat{N}} \). The discretized birth term, \( \hat{B}_{iCA} \), and death term, \( \hat{D}_{iCA} \), obtained from the cell average technique are defined below. These are the \( i \)th components of the vectors \( \mathbf{B} \) and \( \mathbf{D} \) respectively. Let us consider the Heaviside function

\[
H(x) := \begin{cases} 
1 & \text{if } x > 0, \\
\frac{1}{2} & \text{if } x = 0, \\
0 & \text{if } x < 0.
\end{cases}
\]

and

\[
\lambda_i^\pm(x) = \frac{x - x_{i+1}}{x_i - x_{i+1}}.
\]

Then the birth and death terms are given as

\[
\hat{B}_{iCA} := \hat{B}_{i-1} \lambda_i^-(\tau_{i-1}) H(\tau_{i-1} - x_{i-1}) + \hat{B}_i \lambda_i^+(\tau_i) H(\tau_i - x_i) + \hat{B}_{i+1} \lambda_i^+(\tau_{i+1}) H(x_{i+1} - \tau_{i+1})
\]

and

\[
\hat{D}_{iCA} := \hat{D}_i = N_i(t) \sum_{j=1}^I \beta(x_i, x_j) \dot{N}_j(t).
\]

The first and the fourth terms on the right hand side of equation (2.15) can be set to zero for \( i = 1 \) and \( i = I \), respectively. The detailed formulation can be found in [19]. By using (2.6) and (2.7) the cell average technique (2.11) can be written as

\[
\frac{d\hat{N}_i(t)}{dt} = \lambda_i^-(\tau_{i-1}) H(\tau_{i-1} - x_{i-1}) \times \sum_{j\geq k} \left( 1 - \frac{1}{2} \delta_{j,k} \right) \beta(x_k, x_j) \dot{N}_j(t) \hat{N}_k(t) + [\lambda_i^+(\tau_i) H(\tau_i - x_i) + \lambda_i^-(\tau_i) H(x_i - \tau_i)] \times \sum_{j\geq k} \left( 1 - \frac{1}{2} \delta_{j,k} \right) \beta(x_k, x_j) \dot{N}_j(t) \hat{N}_k(t) + \lambda_i^+(\tau_{i+1}) H(x_{i+1} - \tau_{i+1}) \times \sum_{j\geq k} \left( 1 - \frac{1}{2} \delta_{j,k} \right) \beta(x_k, x_j) \dot{N}_j(t) \hat{N}_k(t) - \hat{N}_i(t) \sum_{j=1}^I \beta(x_i, x_j) \dot{N}_j(t).
\]

It should be pointed out here that in this work we consider the following discrete norm

\[
\|\mathbf{N}\| = \sum_{i=1}^I |N_i|.
\]
The following lemma is required to show the convergence of the scheme to solve (1.2):

**Lemma 2.1.** Assume that the coagulation kernel and the initial datum satisfy
\[
\beta \in W^{2,\infty}((0, R) \times (0, R)) \quad \text{and} \quad n^{\text{in}} \in W^{2,\infty}(0, R).
\]

Then there exists a constant \( L(T, R) > 0 \) such that
\[
\|n(t)\|_{W^{2,\infty}(0, R)} \leq L(T, R).
\]

**Proof.** In [16], it is shown that there exists a weak solution \( n \in L^{\infty}((0, T); L^{1}(0, R)) \) to (1.2) with the suitable initial datum \( n^{\text{in}} \). Let \( \| \cdot \|_{\infty, 1} \) denotes the norm in \( L^{\infty}((0, T); L^{1}(0, R)) \). From (2.18), we can also say that
\[
\beta \in W^{1,\infty}((0, R) \times (0, R)) \quad \text{and} \quad n^{\text{in}} \in W^{1,\infty}(0, R).
\]

Hence, by Proposition 3.6 in [1], there exists a \( C(T, R) > 0 \) such that
\[
\|n(t)\|_{W^{1,\infty}(0, R)} \leq C(T, R).
\]

In order to prove (2.19), we use (2.20) and (2.18).

First, we integrate equation (1.2) with respect to \( t \) and then differentiate it twice with respect to \( x \) to obtain
\[
\frac{\partial^2 n(t, x)}{\partial x^2} = \frac{\partial^2 n_0(x)}{\partial x^2} + \int_{0}^{t} \left[ \frac{1}{2} \int_{0}^{x} \left( \frac{\partial^2 \beta(x - y, y)}{\partial x^2} n(x - y, s)n(y, s) + \beta(x - y, y) \frac{\partial^2 n(x - y, s)}{\partial x^2} n(y, s) \right) dy 
+ \frac{1}{2} \frac{\partial \beta(x - y, y)}{\partial x} \bigg|_{y=x} n(x, s)n(0, s) - \int_{0}^{R} \left( \frac{\partial^2 \beta(x, y)}{\partial x^2} n(x, s)n(y, s) 
+ \beta(x, y) \frac{\partial^2 n(x, s)}{\partial x^2} n(y, s) \right) dy \right] ds.
\]

Taking the maximum value over all possible values of \( x \), we find
\[
\left\| \frac{\partial^2 n(t, x)}{\partial x^2} \right\|_{L^\infty} \leq \left\| \frac{\partial^2 n_0(x)}{\partial x^2} \right\|_{L^\infty} + \left\{ \frac{3}{2} \left\| \beta \right\|_{W^{2,\infty}} \left\| n \right\|_{L^\infty} \| n \|_{\infty, 1} + \frac{1}{2} \left\| \beta \right\|_{W^{1,\infty}} \left\| n \right\|_{L^\infty}^2 \right\} t
+ 3 \left\| \beta \right\|_{W^{1,\infty}} \left\| n \right\|_{\infty, 1} \int_{0}^{t} \left\| \frac{\partial n}{\partial x} \right\|_{L^\infty} ds
+ \frac{3}{2} \left\| \beta \right\|_{L^\infty} \left\| n \right\|_{\infty, 1} \int_{0}^{t} \left\| \frac{\partial^2 n}{\partial x^2} \right\|_{L^\infty} ds.
\]

(2.21)

Owing to (2.20), we thank Gronwall’s lemma which gives us (2.19). \qed

Before moving to the main result, let us recall some definitions and a result taken from [18].

**Definition 2.2.** The **local discretization error** is defined by the residual left by substituting the exact solution \( N(t) \) into equation (2.12) as
\[
\sigma(t) = \frac{dN(t)}{dt} - \left( \hat{B}(N(t)) - \hat{D}(N(t)) \right).
\]
The scheme (2.12) is called consistent of order \( p \) if, for \( \Delta x \to 0 \),

\[
\| \sigma(t) \| = O(\Delta x^p), \quad \text{uniformly for all} \quad t, \quad 0 \leq t \leq T.
\]

**Definition 2.3.** The **global discretization error** is defined by

\[ (2.23) \quad \epsilon(t) = N(t) - \hat{N}(t). \]

The scheme (2.12) is called convergent of order \( p \) if, for \( \Delta x \to 0 \),

\[
\| \epsilon(t) \| = O(\Delta x^p), \quad \text{uniformly for all} \quad t, \quad 0 \leq t \leq T.
\]

It is important that the solution obtained by CAT remains non-negative for all times. This can be easily shown by using the next well known theorem. In the following theorem we write \( \hat{M} \geq 0 \) for a vector \( \hat{M} \in \mathbb{R}^I \) if all of its components are non-negative.

**Theorem 2.4.** Suppose that \( \hat{F}(t, \hat{M}) \) defined in (2.12) is continuous and satisfies the Lipschitz condition as

\[
\| \hat{F}(t, \hat{P}) - \hat{F}(t, \hat{M}) \| \leq L\| \hat{P} - \hat{M} \| \quad \text{for all} \quad \hat{P}, \hat{M} \in \mathbb{R}^I.
\]

Then the solution of the semi-discrete system (2.12) is non-negative if and only if for any vector \( \hat{M} \in \mathbb{R}^I \) with \( \hat{M} \geq 0 \), the condition \( \hat{M}_i = 0 \) implies \( \hat{F}_i(t, \hat{M}) \geq 0 \) for any \( i = 1, \ldots, I \) and all \( t \geq 0 \).

**Proof.** The proof can be found in [18, Chap. 1, Theorem 7.1].

The following theorem is required to show the convergence of the CAT.

**Theorem 2.5.** Let us assume that the Lipschitz conditions on \( \hat{B}(N(t)) \) and \( \hat{D}(N(t)) \) are satisfied for \( 0 \leq t \leq T \) and for all \( N, \hat{N} \in \mathbb{R}^I \) where \( N \) and \( \hat{N} \) are the projected exact and numerical solutions defined in (2.5) and (2.12) respectively. Then a consistent discretization method is also convergent and the convergence is of the same order as the consistency.

**Proof.** The proof is similar to Theorem 2.4 in [17].

Now we shall state the main result of the paper.

**Theorem 2.6.** Under the assumptions of Lemma 2.1, the CAT for solving (1.2) is second order convergent on a uniform and first order convergent on a non-uniform smooth (geometric) grid.

**Proof.** This result can easily be proved by applying Theorem 2.5. In order to fulfill the requirements of Theorem 2.5, for the convergence of the CAT, it is shown in Section 3 that the scheme is second order consistent on a uniform grid and first order consistent on a non-uniform smooth (geometric) grid. Moreover, in Section 4, the birth \( \hat{B}(N(t)) \) and death \( \hat{D}(N(t)) \) terms satisfy the Lipschitz conditions.
3. Consistency

Let us describe the four main sections to study the consistency of the CAT for solving SCE (1.2). First, we evaluate the discretization error of the integrated birth and death terms in Section 3.1 and 3.2, respectively. Then all error terms are summarized, in Section 3.3, to obtain the local discretization error. Finally, in Section 3.4, the two different types of grids are considered to evaluate the order of consistency of the CAT.

3.1. Discretization error in the birth term. The integrated birth term of SCE (1.2) over the $i$th cell is given by

$$B_i = \frac{1}{2} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_0^x \beta(x - y, y)n(t, x - y)n(t, y)dydx.$$  

By changing the order of integration we get

$$B_i = \frac{1}{2} \sum_{j=1}^{i-1} \int_{x_{j-1/2}}^{x_{j+1/2}} \int_{x_{i-1/2}}^{x_{i+1/2}} \beta(x - y, y)n(t, x - y)n(t, y)dxdy$$

$$+ \frac{1}{2} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_y^{x_{i-1/2}} \beta(x - y, y)n(t, x - y)n(t, y)dxdy.$$  

Now we apply the midpoint rule to the outer integrals in both terms on the right-hand side and use the relationship $N_i = n(t, x_i)\Delta x_i + \mathcal{O}(\Delta x^3)$ for the midpoint rule to obtain

$$B_i = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}}^{x_{i+1/2}} \beta(x - x_j, x_j)n(t, x - x_j)dx$$

$$+ \frac{1}{2} N_i(t) \int_{x_i}^{x_{i+1/2}} \beta(x - x_i, x_i)n(t, x - x_i)dx + \mathcal{O}(\Delta x^3),$$  

$$=: \tilde{B}_i + \mathcal{O}(\Delta x^3).$$  

Let us denote the integral terms in $\tilde{B}_i$ by $I_1$ and $I_2$, respectively, and evaluate them separately.

**Integral term $I_1$:** We consider the first integral term on the right-hand side in (3.1) and use the substitution $x - x_j = x'$ to get

$$I_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}-x_j}^{x_{i+1/2}-x_j} \beta(x', x_j)n(t, x')dx'.$$

We now define $l_{i,j}$ and $\gamma_{i,j}$ to be those indices such that the following hold

$$x_{i-1/2} - x_j \in \Lambda_{l_{i,j}} \text{ and } \gamma_{i,j} := \text{sgn}[(x_{i-1/2} - x_j) - x_{l_{i,j}}],$$

where

$$\text{sgn}(x) := \begin{cases} 1 & \text{if } x > 0, \\ 0 & \text{if } x = 0, \\ -1 & \text{if } x < 0. \end{cases}$$
By the definition of the indices $l_{i,j}$ and $\gamma_{i,j}$ in (3.3), the equation (3.2) can be rewritten as

\begin{equation}
I_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}-x_j}^{x_{i+1/2}-x_j} \beta(x', x_j) n(t, x') dx' \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \sum_{k=l_{i,j} + \frac{1}{2}(\gamma_{i,j}-1)}^{l_{i+1,j} + \frac{1}{2}(\gamma_{i+1,j}-1)} \int_{x_{k-1/2}}^{x_{k+1/2}} \beta(x', x_j) n(t, x') dx' \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i+1/2}-x_j}^{x_{i+1/2}+\frac{1}{2}(\gamma_{i,j})} \beta(x', x_j) n(t, x') dx'.
\end{equation}

Let $p$ be the total number of terms in the following sum

\[ \sum_{k=l_{i,j} + \frac{1}{2}(\gamma_{i,j})}^{l_{i+1,j} + \frac{1}{2}(\gamma_{i+1,j}-1)} \int_{x_{k-1/2}}^{x_{k+1/2}} \beta(x', x_j) n(t, x') dx'. \]

In particular, let $p := \#\{ n : l_{i,j} + \frac{1}{2}(\gamma_{i,j} + 1) \leq n \leq l_{i+1,j} + \frac{1}{2}(\gamma_{i+1,j} - 1) \}$ and set

\[ k_1 := l_{i,j} + \frac{1}{2}(\gamma_{i,j} + 1), \quad k_2 := k_1 + 1, \ldots, \quad k_{p-1} := k_1 + (p - 2). \]

Next, we shall show that $p$ is finite and can be estimated by a constant which is independent of the grid size. By using the definition of the indices $l_{i,j}$ and $\gamma_{i,j}$ in (3.3), we can estimate

\[ (p - 2) \Delta x_{\min} \leq \Delta x_{k_2} + \Delta x_{k_3} + \ldots + \Delta x_{k_{p-1}} \leq \frac{1}{2} (\Delta x_i + \Delta x_{i+1}) \leq \Delta x \]

which implies using the assumption of quasi uniformity (2.1) that

\[ (p - 2) \leq \frac{\Delta x}{\Delta x_{\min}} \leq K \Rightarrow p \leq K + 2. \]

This means the above sum has uniformly bounded finite number of terms. So we can apply the midpoint rule to the integral in second term on the right hand side and use $N_k(t) = n(t, x_k) \Delta x_k + \mathcal{O}(\Delta x^3)$ to get

\begin{equation}
I_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}-x_j}^{x_{i+1/2}-x_j} \beta(x', x_j) n(t, x') dx' \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \sum_{x_{i-1/2} \leq x_j + x_k < x_{i+1/2}} \beta(x', x_j) N_k(t) \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i+1/2}-x_j}^{x_{i+1/2}+\frac{1}{2}(\gamma_{i,j})} \beta(x', x_j) n(t, x') dx' + \mathcal{O}(\Delta x^3).
\end{equation}

**Integral term $I_2$:** Let us consider the second integral term in (3.1) and use the substitution $x - x_i = x'$ to estimate

\[ I_2 = \frac{1}{2} N_i(t) \int_0^{x_{i+1/2}-x_i} \beta(x', x_i) n(t, x') dx. \]
Again by the definition of the indices \( l_{i,j} \) and \( \gamma_{i,j} \) in (3.3) we split the above integral as

\[
I_2 = \frac{1}{2} N_i(t) \sum_{k=1}^{l_{i+1,i}+\frac{1}{2}(\gamma_{i+1,i}-1)} \int_{x_{k-1/2}}^{x_{k+1/2}} \beta(x', x_i) n(t, x') dx' + \frac{1}{2} N_i(t) \int_{l_{i+1,i}+\frac{1}{2} \gamma_{i+1,i}}^{x_{i+1/2}-x_i} \beta(x', x_i) n(t, x') dx' + O(\Delta x^3).
\]

By applying the midpoint rule in the first term and using the definition of the indices \( l_{i,j} \) and \( \gamma_{i,j} \), we get

\[
I_2 = \frac{1}{2} N_i(t) \sum_{x_i+k<x_{i+1/2}} \beta(x_k, x_i) N_k(t)
\]

By substituting (3.5), (3.6) into (3.1) and using (2.6), we estimate

\[
B_i = B_i + \frac{1}{2} \sum_{j=1}^{j-1} N_j(t) \int_{x_{i-1/2}}^{x_{i+1/2}} \beta(x', x_j) n(t, x') dx' + \frac{1}{2} N_i(t) \int_{x_{i+1/2}-x_j}^{x_{i+1/2}} \beta(x', x_j) n(t, x') dx' + O(\Delta x^3).
\]

Let us denote the sum of the remaining two integrals on the right hand side in (3.7) by the error \( E_1 \) which will be discussed later.

Now we concentrate to evaluate the integrated term \( V_i - x_iB_i \) by using (2.3) and (2.8) as follows

\[
V_i - x_iB_i = \frac{1}{2} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_0^x (x-x_i) \beta(x-y, y) n(t, x-y) n(t, y) dy dx.
\]

By changing the order of integration we get

\[
V_i - x_iB_i = \frac{1}{2} \sum_{j=1}^{j-1} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_{x_{i-1/2}}^{x_{i+1/2}} (x-x_i) \beta(x-y, y) n(t, x-y) n(t, y) dx dy + \int_{x_{i-1/2}}^{x_{i+1/2}} \int_y^{x_{i+1/2}} (x-x_i) \beta(x-y, y) n(t, x-y) n(t, y) dx dy.
\]

Now applying the midpoint rule to the outer integrals in both the terms on the right hand side and using the relationship \( N_i = n(t, x_i) \Delta x_i + O(\Delta x^3) \) with \( \beta(0, \cdot) = 0 \), we obtain

\[
V_i - x_iB_i = \frac{1}{2} \sum_{j=1}^{j-1} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_{x_{i-1/2}}^{x_{i+1/2}} (x-x_i) \beta(x-x_j, x_j) n(t, x-x_j) dx
\]

\[
= \frac{1}{2} \sum_{j=1}^{j-1} \int_{x_{i-1/2}}^{x_{i+1/2}} \int_{x_{i-1/2}}^{x_{i+1/2}} (x-x_i) \beta(x-x_j, x_j) n(t, x-x_j) dx + O(\Delta x^3),
\]

\[
= V_i - x_iB_i + O(\Delta x^3).
\]
We denote the integral terms involving in \( \tilde{V}_i - x_i \tilde{B}_i \) by \( P_1 \) and \( P_2 \), respectively, and calculate them separately.

**Integral term** \( P_1 \): Let us consider the first integral term in (3.8) and insert \( x - x_j = x' \) to estimate

\[
(3.9) \quad P_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}-x_j}^{x_{i+1/2}-x_j} (x' - x_j) \beta(x', x_j) n(t, x') dx'.
\]

By the definition of the indices \( l_{i,j} \) and \( \gamma_{i,j} \) in (3.3), (3.9) can be rewritten as

\[
P_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}-x_j}^{x_{i+1/2}-x_j} (x' - x_j) \beta(x', x_j) n(t, x') dx' \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \sum_{k=l_{i,j}+\frac{1}{2} \gamma_{i,j}+1}^{l_{i+1,j}+\frac{1}{2} \gamma_{i+1,j}} \int_{x_{k-1/2}}^{x_{k+1/2}} (x' - x_j) \beta(x', x_j) n(t, x') dx' \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i+1/2}-x_j}^{x_{i+1/2}-x_j} (x' - x_j) \beta(x', x_j) n(t, x') dx'.
\]

Since the number of terms in the inner summation of second term on the right hand side is finite as before, therefore we can use the midpoint rule to the integral in second term on the right hand side and use \( N_k(t) = n(t, x_k) \Delta x_k + \mathcal{O}(\Delta x^3) \) to obtain

\[
(3.10) \quad P_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}-x_j}^{x_{i+1/2}-x_j} (x' - x_j) \beta(x', x_j) n(t, x') dx' \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \sum_{x_{j+1/2} \leq x_k < x_{i+1/2}} (x_k - x_j) \beta(x_k, x_j) N_k(t) \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{l_{i+1,j}+\frac{1}{2} \gamma_{i+1,j}}}^{x_{l_{i+1,j}+\frac{1}{2} \gamma_{i+1,j}+1}} (x' - x_j) \beta(x', x_j) n(t, x') dx' \\
+ \frac{1}{24} \sum_{j=1}^{i-1} N_j(t) \sum_{k=l_{i,j}+\frac{1}{2} \gamma_{i,j}+1}^{l_{i+1,j}+\frac{1}{2} \gamma_{i+1,j}+1} \Delta x_k^3 \frac{\partial}{\partial x} \{ \beta(x_k, x_j) n(t, x_k) \} \\
+ \mathcal{O}(\Delta x^4).
\]

**Integral term** \( P_2 \): Let us consider the second integral term in (3.8) and use the substitution \( x - x_i = x' \) to estimate

\[
P_2 = \frac{1}{2} N_i(t) \int_{0}^{x_{i+1/2}-x_i} x' \beta(x', x_i) n(t, x') dx.
\]

By the definition of the indices \( l_{i,j} \) and \( \gamma_{i,j} \) in (3.3) we split the above integral as
Using the equation (3.8) and (3.12), we obtain
\begin{equation}
(3.13)
\end{equation}

Now we evaluate each term in (2.15) separately. We begin with the first term without Heaviside function \( H \) and insert the value of \( \lambda \) from (2.14) to get

\[ \lambda_i \nu_{i-1} \hat{B}_{i-1} = \frac{\nu_{i-1} - x_{i-1}}{x_i - x_{i-1}} \hat{B}_{i-1} = \frac{2}{\Delta x_i + \Delta x_{i-1}} [\hat{V}_{i-1} - x_{i-1} \hat{B}_{i-1}]. \]

Using the equation (3.8) and (3.12), we obtain

\begin{equation}
(3.13)
\end{equation}

\[ \lambda_i \nu_{i-1} \hat{B}_{i-1} = \frac{2}{\Delta x_i + \Delta x_{i-1}} \left[ \hat{V}_{i-1} - x_{i-1} \hat{B}_{i-1} \right. \]

\[ - \frac{1}{2} \sum_{j=1}^{i-2} N_j(t) \int_{x_{i-1/2}-x_j}^{x_{i-1/2}-x_j} (x' - x_{i-1} + x_j) \beta(x', x_j) n(t, x') dx' \]

\[ - \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i+1/2}+x_j}^{x_{i+1/2}+x_j} (x' - x_{i-1} + x_j) \beta(x', x_j) n(t, x') dx' \]

\[ - \frac{1}{2} \sum_{j=1}^{i-2} N_j(t) \int_{x_{i+1/2}+x_j}^{x_{i+1/2}+x_j} (x' + 1 + x_j) \beta(x', x_j) n(t, x') dx' \]

\[ + \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i+1/2}+x_j}^{x_{i+1/2}+x_j} (x' - x_{i-1} + x_j) \beta(x', x_j) n(t, x') dx' \]

\[ + \frac{1}{24} \sum_{j=1}^{i-1} N_j(t) \sum_{k=1}^{\nu_{i-1} + \frac{1}{2}(\gamma_{n-1})} \Delta x_k^3 \frac{\partial}{\partial x} \{ \beta(x_k, x_j) n(t, x_k) \} \]

\[ + O(\Delta x^4). \]
In order to solve equation (3.13), we estimate $\tilde{V}_{i-1} - x_{i-1} \tilde{B}_{i-1}$ defined in (3.8) as follows

$$
(3.14) \quad \tilde{V}_{i-1} - x_{i-1} \tilde{B}_{i-1} = \frac{1}{2} \left[ \sum_{j=1}^{i-2} N_j \int_{x_{i-3/2}}^{x_{i-1/2}} (x - x_{i-1}) f(x - x_j, x_j) dx + \int_{x_{i-1}}^{x_{i-1/2}} (x - x_{i-1}) f(x - x_{i-1}, x_{i-1}) n(t, x_{i-1}) \Delta x_{i-1} dx \right],
$$

where $f(\cdot, y) := \beta(\cdot, y)n(t, \cdot)$. Next, we use Taylor series expansions of each integrand about $x_{i-1}$ in equation (3.14) as

$$
(x - x_{i-1}) f(x - x_j, x_j) = 0 + f(x_{i-1} - x_j, x_j)(x - x_{i-1}) + f_x(x_{i-1} - x_j, x_j)(x - x_{i-1})^2 + O(\Delta x^3),
$$

$$
(x - x_{i-1}) f(x - x_{i-1}, x_{i-1}) = 0 + f(x_{i-1} - x_{i-1}, x_{i-1})(x - x_{i-1}) + O(\Delta x^2).
$$

The substitution of the above Taylor series expansion in equation (3.14) gives

$$
\tilde{V}_{i-1} - x_{i-1} \tilde{B}_{i-1} = \frac{1}{2} \left[ \sum_{j=1}^{i-2} N_j f_x(x_{i-1} - x_j, x_j) \Delta x_{i-1}^3 + \frac{1}{8} f(x_{i-1} - x_{i-1}, x_{i-1}) n(t, x_{i-1}) \Delta x_{i-1}^3 + O(\Delta x^4) \right].
$$

Since $\beta(x_{i-1} - x_{i-1}, x_{i-1}) = \beta(0, x_{i-1}) = 0$, therefore we have $f(x_{i-1} - x_{i-1}, x_{i-1}) = 0$. This implies that

$$
\tilde{V}_{i-1} - x_{i-1} \tilde{B}_{i-1} = \frac{1}{24} \sum_{j=1}^{i-2} N_j f_x(x_{i-1} - x_j, x_j) \Delta x_{i-1}^3 + O(\Delta x^4).
$$

Again the application of Taylor series expansion gives us

$$
(3.15) \quad \tilde{V}_{i-1} - x_{i-1} \tilde{B}_{i-1} = \frac{1}{24} \sum_{j=1}^{i-2} N_j f_x(x_i - x_j, x_j) \Delta x_{i-1}^3 + O(\Delta x^4).
$$

Finally, substituting (3.15) into (3.13), we obtain

$$
(3.16) \quad \lambda_{i-1}^-(\pi_{i-1}) \tilde{B}_{i-1} = \frac{1}{12} \sum_{j=1}^{i-2} N_j f_x(x_i - x_j, x_j) \frac{\Delta x_{i-1}^3}{\Delta x_{i-1} + \Delta x_{i-1}^3}
$$

$$
- \frac{1}{24} \sum_{j=1}^{i-2} N_j \left( \int_{x_{i-3/2} - x_j}^{x_{i-1/2} - x_j} \frac{(x' - x_{i-1} + x_j)}{\Delta x_{i-1} + \Delta x_{i-1}^3} f(x', x_j) dx' \right)
$$

$$
- \frac{1}{24} \sum_{j=1}^{i-1} N_j \left( \int_{x_{i-1/2} - x_j}^{x_{i-1} - x_j} \frac{x' - x_{i-1} + x_j}{\Delta x_{i-1} + \Delta x_{i-1}^3} f(x', x_j) dx' \right)
$$

$$
- \frac{1}{24} \sum_{j=1}^{i-2} N_j \left( \int_{x_{i-1} + \frac{1}{2} \gamma_{i-1,j}}^{x_{i-1} + \frac{1}{2} \gamma_{i-1,j} - \frac{1}{2}} \frac{\Delta x_k^3}{\Delta x_{i-1} + \Delta x_{i-1}^3} f(x_k, x_j) dx' \right)
$$

$$
+ O(\Delta x^3).
$$
Next, the second term in (2.15) is evaluated as

\[
\lambda_i^+ (\pi_i) \hat{B}_i = \frac{\Bar{v}_i - x_{i+1}}{x_i - x_{i+1}} \hat{B}_i = \left(1 - \frac{\Bar{v}_i - x_i}{x_{i+1} - x_i}\right) \hat{B}_i = \hat{B}_i - \frac{2}{\Delta x_{i+1} + \Delta x_i} (\Bar{v}_i - x_i \hat{B}_i).
\]

Calculating as before, we estimate the above expression in the following form

\[
\lambda_i^+ (\pi_i) \hat{B}_i = \hat{B}_i - \frac{1}{12} \sum_{j=1}^{i-1} N_j f(x_i - x_j, x_j) \frac{\Delta x_i^3}{x_i + \Delta x_{i+1}} \]

\[
+ \sum_{j=1}^{i-1} N_j (t) \int_{x_i-1/2-x_j}^{x_i+1/2-x_j} \frac{(x' - x_i + x_j)}{x_i + \Delta x_{i+1}} f(x', x_j) dx'
\]

\[
+ \sum_{j=1}^{i-1} N_j (t) \int_{x_i+1/2-x_j}^{x_i+1/2-x_j} \frac{(x' - x_i + x_j)}{x_i + \Delta x_{i+1}} f(x', x_j) dx'
\]

\[
+ \frac{1}{12} \sum_{j=1}^{i-1} N_j (t) \sum_{k=l_{i,j} + \frac{1}{2} (\gamma_{i,j} + 1)} [x_i + \Delta x_{i+1}]^{-1} f(x', x_j) + \mathcal{O}(\Delta x^3).
\]

Similar to the second term we obtain

\[
\lambda_i^- (\pi_i) \hat{B}_i = \hat{B}_i + \frac{1}{12} \sum_{j=1}^{i-1} N_j f(x_i - x_j, x_j) \frac{\Delta x_i^3}{x_i + \Delta x_{i-1}} \]

\[
- \sum_{j=1}^{i-1} N_j (t) \int_{x_i-1/2-x_j}^{x_i+1/2-x_j} \frac{(x' - x_i + x_j)}{x_i + \Delta x_{i-1}} f(x', x_j) dx'
\]

\[
- \sum_{j=1}^{i-1} N_j (t) \int_{x_i+1/2-x_j}^{x_i+1/2-x_j} \frac{(x' - x_i + x_j)}{x_i + \Delta x_{i-1}} f(x', x_j) dx'
\]

\[
- \frac{1}{12} \sum_{j=1}^{i-1} N_j (t) \sum_{k=l_{i,j} + \frac{1}{2} (\gamma_{i,j} + 1)} [x_i + \Delta x_{i-1}]^{-1} f(x', x_j) + \mathcal{O}(\Delta x^3).
\]

Finally, similar to the first term we can easily estimate

\[
\lambda_i^+ (\pi_{i+1}) \hat{B}_{i+1} = \frac{1}{12} \sum_{j=1}^{i} N_j f(x_i - x_j, x_j) \frac{\Delta x_i^3 + 1}{x_i + \Delta x_{i+1}} \]

\[
+ \sum_{j=1}^{i} N_j (t) \int_{x_{i+1/2-x_j}}^{x_i+1/2-x_j} \frac{(x' - x_i + 1 + x_j)}{x_i + \Delta x_{i+1}} f(x', x_j) dx'
\]

\[
+ \sum_{j=1}^{i+1} N_j (t) \int_{x_{i+1/2-x_j}}^{x_i+1/2-x_j} \frac{(x' - x_i + 1 + x_j)}{x_i + \Delta x_{i+1}} f(x', x_j) dx'
\]

\[
+ \frac{1}{12} \sum_{j=1}^{i} N_j (t) \sum_{k=l_{i+1,j} + \frac{1}{2} (\gamma_{i+1,j} + 1)} [x_i + \Delta x_{i+1}]^{-1} f(x', x_j) + \mathcal{O}(\Delta x^3).
\]
By substituting (3.16), (3.17), (3.18) and (3.19) into (2.15) and using (3.7), the local discretization error can be evaluated as follows

Case I: \( \nu_{i-1} > x_{i-1}, \nu_i > x_i \) and \( \nu_{i+1} \geq x_{i+1} \):

\[
\dot{B}^{CA}_i = B_i - \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2} - x_j}^{x_{i,j} + \frac{1}{2} \gamma_{i,j}} f(x', x_j) dx' - \frac{1}{2} \sum_{j=1}^{i} N_j(t) \int_{x_{i,j} + \frac{1}{2} \gamma_{i,j}}^{x_{i+1/2} - x_j} f(x', x_j) dx' \]

\[
+ \frac{1}{12} \left( \frac{\Delta x_{i-1}^3}{\Delta x_i + \Delta x_{i-1}} - \frac{\Delta x_i^3}{\Delta x_i + \Delta x_{i+1}} \right) \sum_{j=1}^{i} N_j f_x'(x_i - x_j, x_j) \]

\[
=: E_1
\]

\[
+ \sum_{j=1}^{i} N_j(t) \int_{x_{i-1/2} - x_j}^{x_{i,j} + \frac{1}{2} \gamma_{i,j}} \frac{(x' - x_i + x_j)}{\Delta x_i + \Delta x_{i+1}} f(x', x_j) dx' \]

\[
+ \sum_{j=1}^{i} N_j(t) \int_{x_{i,j} + \frac{1}{2} \gamma_{i,j}}^{x_{i+1/2} - x_j} \frac{(x' - x_i + x_j)}{\Delta x_i + \Delta x_{i+1}} f(x', x_j) dx' \]

\[
- \sum_{j=1}^{i-2} N_j(t) \int_{x_{i-1/2} - x_j}^{x_{i,j} + \frac{1}{2} \gamma_{i,j}} \frac{(x' - x_{i-1} + x_j)}{\Delta x_i + \Delta x_{i-1}} f(x', x_j) dx' \]

\[
- \sum_{j=1}^{i-1} N_j(t) \int_{x_{i,j} + \frac{1}{2} \gamma_{i,j}}^{x_{i+1/2} - x_j} \frac{(x' - x_i + x_j)}{\Delta x_i + \Delta x_{i-1}} f(x', x_j) dx' \]

\[
+ \frac{1}{12} \sum_{k=i_{j+1} + \frac{1}{2} (\gamma_{i,j} + 1)}^{i_{i+1,j} + \frac{1}{2} (\gamma_{i,j} + 1)} \frac{\Delta x_k^3}{\Delta x_i + \Delta x_{i+1}} f_{x'}(x_k, x_j) \]

\[
- \frac{1}{12} \sum_{k=i_{j+1} + \frac{1}{2} (\gamma_{i,j} + 1)}^{i_{i+1,j} + \frac{1}{2} (\gamma_{i,j} + 1)} \frac{\Delta x_k^3}{\Delta x_i + \Delta x_{i-1}} f_{x'}(x_k, x_j) \]

\[
+ \mathcal{O}(\Delta x^3),
\]

where \( E_1, E_2, E_3, \) and \( E_4 \) are the error terms.

Case II: \( \nu_{i-1} \leq x_{i-1}, \nu_i < x_i \) and \( \nu_{i+1} < x_{i+1} \): Similar to the previous case, we have

\[
\dot{B}^{CA}_i = B_i + E_1 + E_2 + E_3 + E_4 + \mathcal{O}(\Delta x^3),
\]

where the error \( E_2 \) will have the same expression as \( E_2 \), defined in (3.20), except only two terms \( \Delta x_{i-1}^3 \) and \( \Delta x_i^3 \) which are, respectively, replaced by \( \Delta x_{i-1}^3 \) and \( \Delta x_{i+1}^3 \). The expressions for \( E_3 \) and \( E_4 \) can easily be written as \( E_3 \) and \( E_4 \), respectively, just with the replacement of \( i \) by \( i + 1 \) except in the denominators involved in \( E_3 \) and \( E_4 \).

Case III: \( \nu_{i-1} \leq x_{i-1}, \nu_i = x_i \) and \( \nu_{i+1} \geq x_{i+1} \)

\[
\dot{B}^{CA}_i = B_i + E_1 + \mathcal{O}(\Delta x^3).
\]
3.2. Discretization error in the death term. Next, the discretization error for death term is calculated in the $i$th cell. From equation (2.4), the integrated death term can be written as follows

$$D_i = \int_{x_{i-1/2}}^{x_{i+1/2}} \int_{x_{j-1/2}}^{x_{j+1/2}} K(x, y)n(t, y)n(t, x)dydx.$$  

The application of the midpoint rule to the outer and inner integrals gives us

$$D_i = N_i(t) \sum_{j=1}^{I} K(x_i, x_j)N_j(t) + O(\Delta x^3) = \hat{D}_i + O(\Delta x^3).$$  

(3.23)

3.3. Summary of all terms. From the equations (3.20-3.22) and (3.23), we can estimate the local discretization error $\sigma_i(t) = (B_i - D_i) - (\hat{B}_{iCA} - \hat{B}_{iCA})$ as

$$\sigma_i(t) = \begin{cases} E_1 + E_2 + E_3 + E_4 + O(\Delta x^3) & \text{if } i \in \mathcal{A}_1, \\ E_1 + E_2^* + E_3^* + E_4^* + O(\Delta x^3) & \text{if } i \in \mathcal{A}_2, \\ E_1 + O(\Delta x^3) & \text{if } i \in \mathcal{A}_3. \end{cases}$$  

(3.24)

where

$$\mathcal{A}_1 = \{i \in \mathbb{N} \mid \tilde{v}_{i-1} > x_{i-1}, \tilde{v}_i > x_i, \tilde{v}_{i+1} \geq x_{i+1} \},$$

$$\mathcal{A}_2 = \{i \in \mathbb{N} \mid \tilde{v}_{i-1} \leq x_{i-1}, \tilde{v}_i < x_i, \tilde{v}_{i+1} < x_{i+1} \},$$

$$\mathcal{A}_3 = \{i \in \mathbb{N} \mid \tilde{v}_{i-1} \leq x_{i-1}, \tilde{v}_i = x_i, \tilde{v}_{i+1} \geq x_{i+1} \}.$$  

Here we consider three different cases to find the order of consistency. Then, the order of consistency is given by

$$\|\sigma(t)\| = \sum_{i \in \mathcal{A}_1} |\sigma_i(t)| + \sum_{i \in \mathcal{A}_2} |\sigma_i(t)| + \sum_{i \in \mathcal{A}_3} |\sigma_i(t)|.$$  

(3.25)

3.4. Grids. The following two different types of grids will be considered to find the order of consistency of CAT.

3.4.1. Uniform grids. Let us begin with the case of uniform grids i.e. $\Delta x_i = \Delta x$ and $x_i = (i - 1/2)\Delta x$ for any $i = 1, \ldots, I$. Here, $E_2$ and $E_2^*$ defined in (3.20) and (3.21), respectively, are obviously zero. In case of such uniform grids, we have

$$x_{i-1/2} - x_j = x_{i-j}, \quad x_{i+1/2} - x_j = x_{i-j+1}, \quad \text{and} \quad x_{i-3/2} - x_j = x_{i-j-1}.$$  

By using the definition of indices $l_{i,j}$ and $\gamma_{i,j}$ in (3.3), we calculate

$$x_{i-1/2} - x_j = x_{i-j} \in \Lambda_{l_{i,j}},$$

which gives

$$x_{i-1/2} - x_j = x_{i-j} = x_{l_{i,j}}.$$  

Similarly, we obtain

$$x_{i+1/2} - x_j = x_{i-j+1} = x_{l_{i+1,j}}.$$
and

\[ x_{i-3/2} - x_{j} = x_{i-j-1} = x_{i-1,j}. \]

This shows that \( \gamma_{i-1,j} = \gamma_{i,j} = \gamma_{i+1,j} = 0 \). Therefore, in (3.20)-(3.21), the error terms \( E_1, E_3 \) and \( E_3' \) become zero. It can also be easily realized that \( x_{i-3/2} - x_{j}, x_{i-1/2} - x_{j}, \) and \( x_{i+1/2} - x_{j} \) are the pivot points of the adjacent cells, i.e. \( l_{i-1,j} = (i-j-1)h, l_{i,j} = (i-j)h \) and \( l_{i+1,j} = (i-j+1)h \) respectively. Thus, by substituting the values of all these indices in \( E_4 \) and \( E_4' \) defined in (3.20) and (3.21), respectively, and applying the Taylor series expansion, we obtain \( E_4 = O(\Delta x^3) \) and \( E_4' = O(\Delta x^3) \). Then, from (3.24), we obtain

\[ \sigma_i(t) = O(\Delta x^3) \text{ if } i \in \mathfrak{A}_1, \mathfrak{A}_2, \mathfrak{A}_3. \]

By using (3.25), the order of consistency is thus given by

\[ \| \sigma(t) \| = O(\Delta x^2). \]

Therefore, the cell average technique is second order consistent on uniform grids.

3.4.2. Non-uniform smooth grids. Non-uniform smooth grids can be obtained by applying some smooth transformation to uniform grids. Assume a variable \( \xi \) with uniform grids and a smooth transformation \( x = g(\xi) \) such that \( x_{i+1/2}^\xi = g(\xi_{i+1/2}) \) for any \( i = 1, \ldots, I \) to get non-uniform smooth grids. In this case, we show that the scheme is first order consistent. Let \( h \) be the uniform mesh width in the variable \( \xi \). For such type of smooth grids, Taylor series expansions in smooth transformations give

\[ \Delta x_i = x_{i+1/2} - x_{i-1/2} = g(\xi_i + \frac{h}{2}) - g(\xi_i - \frac{h}{2}) = h g'(\xi_i) + O(h^3). \]

Hence, by calculating \( \Delta x_{i-1} \) and \( \Delta x_{i+1} \) similar to \( \Delta x_i \), we obtain

\[ \Delta x_i = O(h^2), \]

\[ \Delta x_i + \Delta x_{i+1} = h[g'(\xi_i) + g'(\xi_{i+1})] + O(h^3) = 2h g'(\xi_i) + O(h^2), \]

and similarly, we have

\[ \Delta x_i + \Delta x_{i-1} = h[g'(\xi_i) + g'(\xi_{i-1})] + O(h^3) = 2h g'(\xi_i) + O(h^2). \]

In particular, we deal with a special type of non-uniform smooth grids which is known as geometric grids. Such type of grids can be defined as \( x_{i+1/2} = r x_{i-1/2}, r > 1, i = 1, \ldots, I \). An exponential function can be applied on uniform grids as a smooth transformation to construct such type of geometric grids. Mathematically, we write

\[ x_{i+1/2} = \exp(\xi_{i+1/2}) = \exp(h + \xi_{i-1/2}) = \exp(h) \exp(\xi_{i-1/2}) = \exp(h) x_{i-1/2} = r x_{i-1/2}, r > 1. \]

To solve the error terms appearing in (3.24), let us further assume that \( \xi_{11}, \xi_{12}, \xi_{21}, \xi_{22}, \xi_{31} \) and \( \xi_{32} \) are corresponding points on uniform mesh for \( x_{i+1,j+1}^\xi + \frac{1}{2} \gamma_{i+1,j+1}, x_{i+1/2} - x_{j+1}, x_{i,j+1/2}^\xi \),
Further, in case of geometric grids, we have

Let us consider

Therefore, we have

For geometric grids, we have

We first evaluate

Similarly, we estimate

Again, by application of smooth transformation, we can easily obtain

and

All these identities will play an important role to solve the error terms involved in (3.24), which helps us to calculate the order of local discretization error $\sigma_i$.

We first evaluate $E_1$ defined in (3.20) as follows

$$E_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2} - x_j}^{x_{i+1/2} - x_j} f(x, x_j) dx + \frac{1}{2} \sum_{j=1}^{i} N_j(t) \int_{x_{i+1/2} - x_j}^{x_{i+1/2} - x_{j-1}} f(x, x_j) dx.$$
Applying the left and right rectangle rules in the integrals involved in the first and second terms, respectively, on the right-hand side, we estimate

\[
E_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) f(x_{i-1/2} - x_j, x_j)(x_{l_{i,j} + \frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j)
+ \frac{1}{2} \sum_{j=1}^{i} N_j(t) f(x_{i+1/2} - x_j, x_j)(x_{i+1/2} - x_j - x_{l_{i+1,j} + \frac{1}{2} \gamma_{i+1,j}}) + O(\Delta x^2).
\]

Then an application of Taylor’s series expansion about \(x_{i-1/2} = x_{i+1/2}\) in \(f(x_{i-1/2} - x_j)\) gives

\[
E_1 = \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) f(x_{i+1/2} - x_j, x_j)(x_{l_{i,j} + \frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j)
- \frac{1}{2} \sum_{j=1}^{i} N_j(t) f(x_{i+1/2} - x_j, x_j)(x_{l_{i+1,j} + \frac{1}{2} \gamma_{i+1,j}} - x_{i+1/2} + x_j) + O(\Delta x^2).
\]

We replace \(j\) by \(j + 1\) in the second term on the right-hand side and use the relationship \(N_j(t) = n(t, x_j) \Delta x_j + O(\Delta x^3)\) for the midpoint rule. Also, we drop the term which is of second order, and obtain

\[
E_1 = \frac{1}{2} \sum_{j=1}^{i-1} n(t, x_j) \Delta x_j f(x_{i+1/2} - x_j, x_j)(x_{l_{i,j} + \frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j)
- \frac{1}{2} \sum_{j=1}^{i} n(t, x_{j+1}) \Delta x_{j+1} f(x_{i+1/2} - x_{j+1}, x_{j+1})(x_{l_{i+1,j+1} + \frac{1}{2} \gamma_{i+1,j+1}} - x_{i+1/2} + x_{j+1})
+ O(\Delta x^2).
\]

Approximating the function \(x \mapsto n(t, x) f(x_{i+1/2} - x, x)\) at \(x_j\) by \(n(t, x) f(x_{i+1/2} - x, x)\) evaluated at \(x = x_{j+1}\) in the first term, we evaluate

\[
(3.29) E_1 = \frac{1}{2} \sum_{j=1}^{i-1} \left( \Delta x_j (x_{l_{i,j} + \frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j) - \Delta x_{j+1} (x_{l_{i+1,j+1} + \frac{1}{2} \gamma_{i+1,j+1}} - x_{i+1/2} + x_{j+1}) \right)
\times n(t, x_{j+1}) f(x_{i+1/2} - x_{j+1}, x_{j+1}) + O(\Delta x^2).
\]

By using the identities in the beginning of this section, we calculate

\[
(3.30) \Delta x_j = \frac{1}{2} \left( x_{l_{i,j} + \frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j \right) - \Delta x_{j+1} \left( x_{l_{i+1,j+1} + \frac{1}{2} \gamma_{i+1,j+1}} - x_{i+1/2} + x_{j+1} \right)
= \left( \Delta x_j - \Delta x_{j+1} \right) \left( x_{l_{i,j} + \frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j \right)
- \Delta x_{j+1} \left[ \left( x_{l_{i+1,j+1} + \frac{1}{2} \gamma_{i+1,j+1}} - x_{i+1/2} + x_{j+1} \right) - \left( x_{l_{i,j} + \frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j \right) \right]
= O(h^2) \left( h_1 g'(\xi_{22}) + O(h^2) \right) - \left( h g'(\xi_{j+1}) + O(h^3) \right) \left[ h_1 (g'(\xi_{12}) - g'(\xi_{22})) + O(h^2) \right]
= O(h^3) - O(h) \left( h_1 h g'(\xi_{22}) + O(h^2) \right)
= O(h^3).
\]
Therefore, substituting (3.30) in (3.29), we obtain

\begin{equation}
E_1 = O(\Delta x^2).
\end{equation}

Next, let us calculate \( E_3 \) defined in (3.20) as follows

\[
E_3 = \sum_{j=1}^{i-1} N_j(t) \int_{x_{i-1/2}}^{x_{i,j} + \gamma_{i,j}} \frac{(x - x_i + x_j)}{\Delta x_i + \Delta x_{i+1}} f(x, x_j) dx \\
+ \sum_{j=1}^{i} N_j(t) \int_{x_{i,j} + \gamma_{i,j}}^{x_{i+1/2}} \frac{(x - x_i + x_j)}{\Delta x_i + \Delta x_{i+1}} f(x, x_j) dx \\
- \sum_{j=1}^{i-2} N_j(t) \int_{x_{i-3/2}}^{x_{i-1,j} + \gamma_{i-1,j}} \frac{(x - x_i - x_j)}{\Delta x_i + \Delta x_{i-1}} f(x, x_j) dx \\
- \sum_{j=1}^{i-1} N_j(t) \int_{x_{i,j} + \gamma_{i,j}}^{x_{i-1/2}} \frac{(x - x_i - x_j)}{\Delta x_i + \Delta x_{i-1}} f(x, x_j) dx.
\]

Applying the left rectangle rule to the integrals appearing in first and third terms, and the right rectangle rule to the integrals in second and fourth terms, we estimate

\[
E_3 = -\frac{1}{2} \sum_{j=1}^{i-1} N_j(t) f(x_{i,j} - x_j, x_j) \frac{\Delta x_i}{\Delta x_i + \Delta x_{i+1}} (x_{i,j} + \gamma_{i,j} - x_{i-1/2} - x_j) \\
- \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) f(x_{i+1,j} - x_j, x_j) \frac{\Delta x_i}{\Delta x_i + \Delta x_{i+1}} (x_{i+1,j} + \gamma_{i+1,j} - x_{i+1/2} - x_j) \\
+ \frac{1}{2} \sum_{j=1}^{i-2} N_j(t) f(x_{i-3/2} - x_j, x_j) \frac{\Delta x_{i-1}}{\Delta x_i + \Delta x_{i-1}} (x_{i-3/2} + \gamma_{i-1,j} - x_{i-3/2} - x_j) \\
+ \frac{1}{2} \sum_{j=1}^{i-1} N_j(t) f(x_{i-1,j} - x_j, x_j) \frac{\Delta x_{i-1}}{\Delta x_i + \Delta x_{i-1}} (x_{i-1,j} + \gamma_{i-1,j} - x_{i-1/2} - x_j) + O(\Delta x^2).
\]

Let us approximate \( f \) at \((x_{i-3/2} - x_j, x_j)\) by \( f \) expanded around \((x_{i-1/2} - x_j, x_j)\) in the third term and \( f \) at \((x_{i-1/2} - x_j, x_j)\) by \( f \) expanded around \((x_{i+1/2} - x_j, x_j)\) in the fourth term. Further, we replace \( j \) by \( j + 1 \) and \( j - 1 \) respectively in second and third terms. Also, the relationship
\[ N_j(t) = n(t, x_j) \Delta x_j + O(\Delta x^3) \] is used to get

\[
E_3 = -\frac{1}{2} \sum_{j=1}^{i-1} n(t, x_j) \Delta x_j f(x_{i-1/2} - x_j, x_j) \frac{\Delta x_i}{\Delta x_i + \Delta x_{i+1}} (x_{l_{i,j}+\frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j)
- \frac{1}{2} \sum_{j=0}^{i-2} n(t, x_{j+1}) \Delta x_{j+1} f(x_{i+1/2} - x_{j+1}, x_{j+1}) \times \frac{\Delta x_j}{\Delta x_j + \Delta x_{j+1}} (x_{l_{i,j+1}+\frac{1}{2} \gamma_{i,j+1}} - x_{i+1/2} + x_{j+1})
+ \frac{1}{2} \sum_{j=2}^{i-1} n(t, x_{j-1}) \Delta x_{j-1} f(x_{i-1/2} - x_{j-1}, x_{j-1}) \times \frac{\Delta x_{i-1}}{\Delta x_{i-1} + \Delta x_i} (x_{l_{i,j-1}+\frac{1}{2} \gamma_{i,j-1}} - x_{i-3/2} + x_{j-1})
+ \frac{1}{2} \sum_{j=1}^{i-1} n(t, x_{j-1}) \Delta x_{j-1} f(x_{i+1/2} - x_{j-1}, x_{j-1}) \times \frac{\Delta x_{i-1}}{\Delta x_{i-1} + \Delta x_i} (x_{l_{i,j-1}+\frac{1}{2} \gamma_{i,j-1}} - x_{i-1/2} + x_j)
+ O(\Delta x^2).
\]

Without loss of generality, we can drop the terms which are second order accurate. Moreover, we approximate the functions \( x \mapsto n(t, x)f(x_{i+1/2} - x, x) \) at point \( x_j \) by \( n(t, x)f(x_{i+1/2} - x, x) \) evaluated at points \( x = x_{j+1} \) of the first and fourth terms, respectively, to obtain

\[
E_3 = -\frac{1}{2} \sum_{j=2}^{i-1} n(t, x_{j-1}) f(x_{i-1/2} - x_{j-1}, x_{j-1}) \frac{\Delta x_i \Delta x_j}{\Delta x_i + \Delta x_{i+1}} (x_{l_{i,j}+\frac{1}{2} \gamma_{i,j}} - x_{i-1/2} + x_j)
- \frac{1}{2} \sum_{j=1}^{i-2} n(t, x_{j+1}) f(x_{i+1/2} - x_{j+1}, x_{j+1}) \times \frac{\Delta x_j}{\Delta x_j + \Delta x_{j+1}} (x_{l_{i,j+1}+\frac{1}{2} \gamma_{i,j+1}} - x_{i+1/2} + x_{j+1})
+ \frac{1}{2} \sum_{j=2}^{i-1} n(t, x_{j-1}) f(x_{i-1/2} - x_{j-1}, x_{j-1}) \times \frac{\Delta x_{i-1}}{\Delta x_{i-1} + \Delta x_i} (x_{l_{i,j-1}+\frac{1}{2} \gamma_{i,j-1}} - x_{i-3/2} + x_{j-1})
+ \frac{1}{2} \sum_{j=1}^{i-1} n(t, x_{j-1}) f(x_{i+1/2} - x_{j-1}, x_{j-1}) \times \frac{\Delta x_{i-1}}{\Delta x_{i-1} + \Delta x_i} (x_{l_{i,j-1}+\frac{1}{2} \gamma_{i,j-1}} - x_{i-1/2} + x_j)
+ O(\Delta x^2).
\]

Let us denote each summation with the factor \( \frac{1}{2} \) on the right-hand side by \( E_{11}, \ldots, E_{14} \) respectively. Therefore, we can write

\[
(3.32) \quad E_3 = (E_{33} - E_{31}) + (E_{34} - E_{32}) + O(\Delta x^2).
\]
To simplify (3.32), we first calculate $E_{33} - E_{31}$ as follows

\[(3.33) \quad E_{33} - E_{31} = \frac{1}{2} \sum_{j=2}^{i-1} n(t, x_{j-1}) f(x_{i-1/2} - x_{j-1}, x_{j-1}) \times \left\{ \frac{\Delta x_i \Delta x_j}{\Delta x_{i-1}} (x_{i-1,j-1} + \frac{1}{2} \gamma_{i-1,j-1} - x_{i-3/2} + x_{j-1}) \right. \]
\[\left. - \frac{\Delta x_i \Delta x_j}{\Delta x_{i+1}} (x_{i,j} + \frac{1}{2} \gamma_{i,j} - x_{i-1/2} + x_{j}) \right\}.\]

Again by using the identities mentioned in the beginning of this section, we need to estimate the following term for solving (3.33).

\[
\Delta x_{i-1} \Delta x_{j-1} (\Delta x_i + \Delta x_{i+1}) (x_{i-1,j-1} + \frac{1}{2} \gamma_{i-1,j-1} - x_{i-3/2} + x_{j-1})
- \Delta x_i \Delta x_j (\Delta x_{i-1} + \Delta x_{i+1}) (x_{i,j} + \frac{1}{2} \gamma_{i,j} - x_{i-1/2} + x_{j})
\]
\[= \Delta x_{i-1} (\Delta x_{j-1} - \Delta x_j) (\Delta x_i + \Delta x_{i+1}) (x_{i-1,j-1} + \frac{1}{2} \gamma_{i-1,j-1} - x_{i-3/2} + x_{j-1})
+ \Delta x_j (\Delta x_{i-1} + \Delta x_{i+1}) (x_{i,j} + \frac{1}{2} \gamma_{i,j} - x_{i-1/2} + x_{j})
- \Delta x_i (\Delta x_{i-1} + \Delta x_{i+1}) (x_{i,j} + \frac{1}{2} \gamma_{i,j} - x_{i-1/2} + x_{j})
\]
\[= O(h^5) + (hg'(\xi_i) + O(h^3)) (\underbrace{hg'(\xi_{i-1}) + O(h^3)}_{=O(h^2)} (2hg'(\xi_i) + O(h^2)) (h_1g'(\xi_{32}) + O(h^2))
- (hg'(\xi_i) + O(h^3)) (2hg'(\xi_i) + O(h^2)) (h_1g'(\xi_{32}) + O(h^2))\]
\[= O(h)[2h^2 (g'(\xi_i))^2 h_1 (g'(\xi_{32}) - g'(\xi_{22}))] + O(h^5)
= O(h) \cdot 2h^3 h_1 (g'(\xi_i))^2 g'(\xi_{32}) + O(h^5)
= O(h^5).\]

Inserting this estimate in (3.33), we obtain

\[(3.34) \quad E_{33} - E_{31} = O(h^2).\]

Analogous to (3.34), we can easily show that

\[(3.35) \quad E_{34} - E_{32} = O(h^2).\]

Finally, substituting (3.34) and (3.35) into (3.32), we have

\[(3.36) \quad E_3 = O(\Delta x^2).\]

In a similar way, we can prove that

\[(3.37) \quad E'_3 = O(\Delta x^2).\]

Next, it can be easily observed from (3.20) and (3.21) that the error terms $E_2$, $E'_2$, $E_4$ and $E'_4$ are second order accurate independent of meshes. Therefore, by substituting (3.31), (3.36) and (3.37) into (3.24), we have

\[\sigma_i(t) = O(\Delta x^2) \quad \text{if} \quad i \in A_1, A_2, A_3.\]
Thus, using (3.25), we obtain

\[ \| \sigma(t) \| = O(\Delta x). \]

This shows that the cell average technique is first order consistent on such type of non-uniform smooth grids.

**Remark 3.1.** It should be pointed out that, due to the cancellation of second order terms, the error terms \( E_2, E_3', E_3, E_4 \) and \( E_4' \) can be shown third order accurate on geometric grids. However, since this will not improve the order of consistency (because \( E_1 \) is only second order accurate for such grids), we do not include further calculations.

## 4. Lipschitz Conditions on \( \hat{B}(N(t)) \) and \( \hat{D}(N(t)) \)

Let us consider the birth term for 0 \( \leq t \leq T \) and for all \( N, \hat{N} \in \mathbb{R}^I \). We get from (2.15)

\[
\| \hat{B}(N) - \hat{B}(\hat{N}) \| \leq \sum_{i=1}^{I} \lambda_i^-(\bar{v}_{i-1}) H(\bar{v}_{i-1} - x_{i-1}) |\hat{B}_{i-1}(N) - \hat{B}_{i-1}(\hat{N})| \\
+ \sum_{i=1}^{I} \lambda_i^+(\bar{v}_i) H(\bar{v}_i - x_i) |\hat{B}_i(N) - \hat{B}_i(\hat{N})| \\
+ \sum_{i=1}^{I} \lambda_i^+(\bar{v}_{i+1}) H(x_{i+1} - \bar{v}_{i+1}) |\hat{B}_{i+1}(N) - \hat{B}_{i+1}(\hat{N})|. 
\]

The definitions of \( \lambda_i^+(x) \) and \( H(x) \) in (2.14) and (2.13), respectively, guarantee that 0 \( \leq \lambda_i^+(x) H(x) \leq 1 \). Thus, by using this upper bound, the above inequality becomes

\[
(4.1) \quad \| \hat{B}(N) - \hat{B}(\hat{N}) \| \leq \sum_{i=1}^{I} |\hat{B}_{i-1}(N) - \hat{B}_{i-1}(\hat{N})| + \sum_{i=1}^{I} |\hat{B}_i(N) - \hat{B}_i(\hat{N})| \\
+ \sum_{i=1}^{I} |\hat{B}_{i+1}(N) - \hat{B}_{i+1}(\hat{N})|. 
\]

Substituting (2.6) into (4.1) and using the assumption on \( \beta \) defined in (2.18), we have

\[
\| \hat{B}(N) - \hat{B}(\hat{N}) \| \leq \frac{1}{2} \| \beta \|_L \sum_{i=1}^{I} \sum_{j=1}^{i-1} \sum_{x_{j+1}/2 \leq x_j < x_{j-1}/2} |N_j(t)N_k(t) - \hat{N}_j(t)\hat{N}_k(t)| \\
+ \frac{1}{2} \| \beta \|_L \sum_{i=1}^{I} \sum_{j=1}^{i} \sum_{x_{j+1}/2 \leq x_j + x_k < x_{j+1}/2} |N_j(t)N_k(t) - \hat{N}_j(t)\hat{N}_k(t)| \\
+ \frac{1}{2} \| \beta \|_L \sum_{i=1}^{I} \sum_{j=1}^{i} \sum_{x_{j+1}/2 \leq x_j + x_k < x_{j+3}/2} |N_j(t)N_k(t) - \hat{N}_j(t)\hat{N}_k(t)| \\
\leq \frac{3}{2} \| \beta \|_L \sum_{j=1}^{I} \sum_{k=1}^{I} |N_j(t)N_k(t) - \hat{N}_j(t)\hat{N}_k(t)|. 
\]
Now we apply the following useful equality $N_j(t)N_k(t) - \hat{N}_j(t)\hat{N}_k(t) = \frac{1}{2}[(N_j(t) + \hat{N}_j(t))(N_k(t) - \hat{N}_k(t)) + (N_j(t) - \hat{N}_j(t))(N_k(t) + \hat{N}_k(t))]$ to get

$$\|\hat{\mathbf{B}}(\mathbf{N}) - \hat{\mathbf{B}}(\hat{\mathbf{N}})\| \leq \frac{3}{4}\|\beta\|_{L^{\infty}} \sum_{j=1}^{I} \sum_{k=1}^{I} \left[ |(N_j(t) + \hat{N}_j(t))|(|N_k(t) - \hat{N}_k(t))| + |(N_j(t) - \hat{N}_j(t))|(|N_k(t) + \hat{N}_k(t))| \right].$$

(4.2)

It can be easily shown that the total number of particles decreases in a coagulation process, i.e.

$$\sum_{j=1}^{I} N_j(t) \leq N_0^T := \text{Total number of particles which are taken initially.}$$

The equation (4.2) can be rewritten as

$$\|\hat{\mathbf{B}}(\mathbf{N}) - \hat{\mathbf{B}}(\hat{\mathbf{N}})\| \leq \frac{3}{2} N_0^T \|\beta\|_{L^{\infty}} \sum_{k=1}^{I} |(N_k(t) - \hat{N}_k(t))| + \sum_{j=1}^{I} |(N_j(t) - \hat{N}_j(t))| \leq C\|\mathbf{N} - \hat{\mathbf{N}}\|,$$

(4.3)

where $C := 3N_0^T \|\beta\|_{L^{\infty}}$. Similarly as before we can easily show the Lipschitz condition for death term as

$$\|\hat{\mathbf{D}}(\mathbf{N}) - \hat{\mathbf{D}}(\hat{\mathbf{N}})\| \leq C\|\mathbf{N} - \hat{\mathbf{N}}\|.$$

(4.4)

Thus, Theorem 2.5 completes the proof of Theorem 2.6.

5. Conclusions

We have presented a detailed convergence analysis of the cell average technique for nonlinear continuous Smoluchowski coagulation equation. It is proved that the cell average technique is second order convergent on uniform grids. However, it gives only a first order convergence on non-uniform smooth geometric grids. In order to obtain a second order convergence on geometric grids, either one needs to adapt a different approach than the one presented here, or modify the error term $E_1$ which may lead to some improvements in the CAT. It is also interesting to analyze CAT for nonlinear continuous SCE on more general grids, which we intend to study in future.
